

TAXONOMIC AND NOMENCLATURAL NOTES ON *HIERACIUM SILESIACUM* (ASTERACEAE)

ZBIGNIEW SZELĄG

Abstract: Lectotypes for the names *Hieracium silesiacum* E. Krause and *H. sparsum* Friv. subsp. *silesiacum* (E. Krause) Zahn var. *vaiskovae* Lengyel & Zahn are designated and illustrated. Based on morphological characteristics, both were found to belong to the same species, of which *H. silesiacum* is the correct name. The distribution of *H. silesiacum* is provided and the hypothetical origin of *Hieracium* sect. *Cernua* in the Western Carpathians and Eastern Sudetes is briefly discussed.

Key words: Asteraceae, *Hieracium* sect. *Cernua*, lectotypification, new synonym, nomenclature, taxonomy, distribution, Eastern Sudetes, Western Carpathians

Zbigniew Szelag, W. Szafer Institute of Botany, Polish Academy of Sciences, Lubicz 46, PL-31-512 Kraków, Poland; e-mail: azszelag@wp.pl

INTRODUCTION

Hieracium silesiacum E. Krause was described from the Hrubý Jeseník Mts [Hohes Gesenke] in the Eastern Sudetes (Krause 1851). It is still the only representative in the Sudetes Mts of the Balkan-Caucasian *H.* sect. *Cernua* R. Uechtr., as redefined by Szelag (2003). Its stations in the Hrubý Jeseník Mts are among the northernmost for the whole section (Bräutigam 1992).

In the 19th century and the first half of the 20th century it was collected in following localities: Velká Kotlina valley [Velký Kotel valley, Grosser Kessel], Mt. Vysoká Hole [Hohe Heide], Mt. Praded [Altvater], Mt. Malý Děd [Leiterberg], Mt. Mravenečník [Ameisenhügel], between Mt. Malý Klín and Mt. Kamzík [Hungerlehne], and from a slope above Domašov village [Tomašov, Thomasdorf]. The species has also been distributed in five exsiccata series: A. Kerner, Fl. Exs. Austro-Hung. no. 201; H. Callier, Fl. Siles. Exs. ed. 1893; Magnier, Fl. Selecta Exs. no. 3308C; H. Zahn, Hieraciotheca Europaea no. 398; and Behr, Herb. Hieraciorum no. 150. According to Fiek & Uechtritz (1881), Formánek (1887), and Oborny (1885, 1906), *H. silesiacum* was abundant only on Mt. Praded, near the springs of the river Opava, while at its other localities it was fairly

scarce. Skřivanek (1956) enumerated three stations only: Velký Kotel valley, Mt. Vysoká Hole, and Mt. Praded at the springs of the Opava. Intensive collecting of the plant for herbaria is perhaps to be blamed for the disappearance of its other previous localities. Nowadays, *H. silesiacum* is a critically endangered species in the Czech Republic (Chrtek jun. 2002). In 2003, Jindřich Chrtek jun. and I observed not more than 50 individuals of the species in the Velká Kotlina valley.

The situation of *Hieracium silesiacum* in the Western Carpathians is less disquieting. It was first found there in 1888 by Josef Freyn, in the Západné Tatry Mts (cf. Sagorski & Schneider 1891), and his specimens (not seen by either Schneider or Sagorski) are still extant in the herbarium of the Natural History Museum in Brno (BRNM). It now has around twenty known populations in the Vysoké Tatry Mts, the Západné Tatry Mts and the Nízke Tatry Mts, most of which have been found recently (Chrtek jun. et al. 2002, 2004).

In Poland, *Hieracium silesiacum* was observed only once (no specimens collected), on 21 Aug. 1968 in the Dolina Tomanowa valley in the West Tatras Mts [Tatry Zachodnie Mts] close to the Slovak-Polish border (Pawlowska & Pawłowski

1970). In spite of a thorough search, its occurrence there could not be confirmed, and I failed to locate any further stations of the species in the Polish part of the Tatra Mts.

Hieracium silesiacum was found to be tetraploid, with a chromosome number of $2n = 36$ counted on plants from the Eastern Sudetes (Chrtek jun. 1996) and Western Carpathians (Chrtek jun. et al. 2004).

***Hieracium silesiacum* E. Krause (Fig. 1)**

Jahresber. Schles. Ges. Vaterl. Kultur **28**: 101, 102. 1851.

≡ *H. sparsum* subsp. *silesiacum* (E. Krause) Zahn in Engler, Das Pflanzenreich **79**: 1026. 1922. – INDICATIO LOCOTYPICA: ‘Diese Form beobachtete ich zuerst im Jahre 1846 im Gesenke am zwei Stellen, an der Hungerlehne und im Kessel. [...] Anfang August dieses Jahres [1850] gelang es mir in Gesellschaft des Director Wimmer, diese Form blühend in Kessel wieder aufzufinden’. – LECTOTYPE (designated here): Kessel im Gesenke, Jul. 1846, E. Krause (ex herb. Krause; WRSL) (Fig. 1). – ICONOGRAPHY: Murr et al. (1904–1906).

= *H. sparsum* subsp. *silesiacum* var. *vaiskovae* Lengyel & Zahn, Magyar Bot. Lapok **31**: 31. 1932, *syn. nov.* – INDICATIO LOCOTYPICA: ‘Zólyom: Vaiskova-Tal bei Alsólehota, Lengyel’ [north Slovakia: Vajskovská dolina valley near Dolná Lehota, leg. G. Lengyel]. – LECTOTYPE (designated here): Comit. Zólyom: in valle Vaiskova ad Alsólehota, 5. Aug. 1929, G. Lengyel (BP 351927) (Fig. 2).

NOTES. *Hieracium sparsum* subsp. *silesiacum* var. *vaiskovae* was described based on a single collection with one blooming and two barren individuals (Fig. 2). Lengyel and Zahn (1932) distinguish it from *H. sparsum* subsp. *silesiacum* proper by its long, minutely denticulate and densely hairy leaves. However, comparison of the original sheet of var. *vaiskovae* with abundant material of *H. silesiacum* from its whole range (Fig. 3), as well as live plants in the wild and in the garden, show that these features fall within the variability of *H. silesiacum* and do not warrant recognition of a distinct taxon. Leaf hairiness changes in the course of ontogeny (the lower stem leaves are most densely hairy, but are missing at anthesis); and the size of leaf teeth varies according to the environment – plants transplanted

to the garden have much longer teeth than those in the wild; similarly, long leaves are characteristic of plants growing in tall grass. When searching the Vajskovská dolina valley in 2003, I found no plants matching the description of *H. sparsum* subsp. *silesiacum* var. *vaiskovae*.

REMARKS ON THE ORIGIN OF *HIERACIUM SILESIACUM*

On the basis of geographical and karyological data, as well as the morphological resemblance of *Hieracium silesiacum* to the other representatives of *H. sect. Cernua*, the following hypotheses may be formulated, pending further phylogenetic analyses and molecular studies now in progress:

1. *Hieracium* sect. *Cernua* in the Western Carpathians and Eastern Sudetes, as well as in the Eastern Alps and Southeastern Carpathians, presumably occurs as a relict going back to a diploid, perhaps pre-Pleistocene sexual species with a wider primary range. This might be either *H. sparsum* Friv., presently occurring in the central part of the Balkan Peninsula, or a closely related, now extinct taxon.

2. The relict range of *H. silesiacum* may be explained by its persistence in glacial refugia in the southern foothills of the Western Carpathians. Colonization of the Eastern Sudetes might then have followed from there. The existence of local glacial refugia in the Eastern Sudetes themselves cannot be ruled out, but seems less probable, as one would expect that long-lasting isolation of the Carpathian and Sudetes populations would have resulted in clear morphological and perhaps karyological differences.

3. The lack of such differences between the populations of the Sudetes and Carpathians suggests a monotypic origin of *H. silesiacum*, and its subsequent expansion into the Western Carpathians (Vysoké-, Západné- and Nízke Tatry Mts) and Eastern Sudetes (Hrubý Jeseník Mts). This would have happened no later than at the end of the last glaciation (Würm), when proper conditions obtained for contact and exchange of the mountain floras of the Carpathians and Sudetes (e.g., Lang 1994).
